Development of transmon qubits for quantum sensing and computing

Andrea Giachero

University of Milano-Bicocca

INFN - Milano-Bicocca

Bicocca Quantum Technologies (BiQuTe) Centre

6.3 Integration of electronic devices:

6.3.1 Superconducting quantum gates:

6.3.1.1 Development of high fidelity universal quantum gates with coupled improved coherence superconducting qubits

M12 **Design of a transmon qubit circuit with feedline and readout resonator (2023)** ✓ 😊

M24 **Fabrication and characterization of transmon qubit circuit with standard aluminum (Al) technology (2024)**
in progress 😊

M36 **Fabrication and characterization of transmon qubit circuit with improved materials for high fidelity quantum gates (2025)**

Activities in synergy with INFN's Qub-IT projects and with ICSC

Quantum Computing

- High-fidelity single- and two-qubit gates are essential building blocks for a fault-tolerant quantum computer;
- Two-qubit gates are formed by coupling together single qubits by using an intermediate electrical coupling circuit (*coupler*);
- Couplers can be implemented as fixed (resonators), tunable (dc-squid, qubit) or parametric (dc-squid) elements;

Science 360, 195-199 (2018)

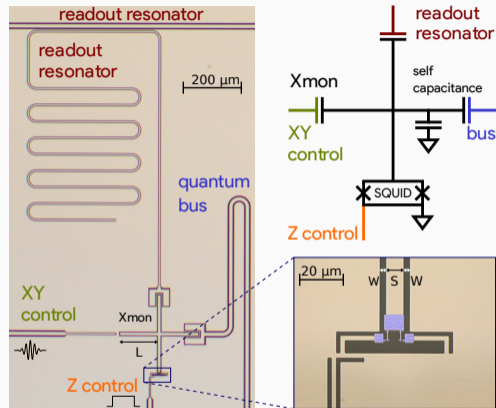

Quantum Sensing

- Single qubit weakly coupled to a high-quality factor cavity can serve as photon storage/detector;
- When photons enter the storage cavity, the qubit undergoes a state change \Rightarrow QND techniques allow for detecting the presence of photons in the cavity without destroying the photon status;
- By utilizing entanglement in a multi-qubit system may lead to overall improved sensitivity;

Phys. Rev. Lett.
126, 141302 (2021)

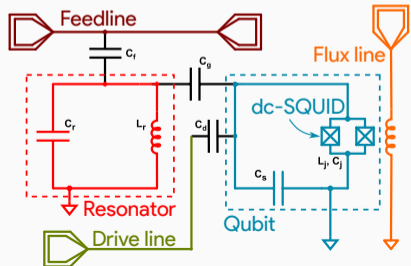

- **Transmon qubit** has become the most widely used superconducting qubit *Nature 549, 242–246 (2017)*
 - transmon regime: $E_J/E_C \sim \mathcal{O}(100)$
 - E_J : Josephson energy
 - E_C : charging energy
 - less sensitive to higher-order effects of the $1/f$ charge noise;
 - less sensitive to the problem of quasiparticle poisoning;
- **Transmon in Xmon form** *Nature 508, 500–503 (2014)*
 - straightforward connectivity: its four arms allow connections with separate elements.
 - ■ resonator for readout;
 - ■ control to excite the qubit state;
 - ■ control to tune the qubit frequency;
 - ■ quantum bus resonator
 - fast control: separate control line *Phys. Rev. Lett. 111, 080502*
 - long coherence: $T_2 \simeq 500 \mu\text{s}$ *npj Quantum Inf 8, 3 (2022)*

Phys. Rev. Lett. 111, 080502

$$E_C = \frac{4e^2}{2C}, \quad E_J = \frac{\hbar I_c}{2e}$$

- **Grounded xmon transmon** [arXiv:2310.05238](https://arxiv.org/abs/2310.05238) [quant-ph]
 - transmission/readout line (feedline) through a $\lambda/4$ resonator;
 - driveline to enable faster qubit control;
 - flux-bias line to tune the energy spacing between the qubit excitation levels;
- **Qubit design** created by using [qiskit-metal](https://github.com/Qiskit/qiskit-metal) (IBM)
 - target Hamiltonian definition;
 - qubit lines and geometry definition;
- **Electromagnetic Simulations** with commercial tools
 - Ansys HFSS for performing the eigenmode simulation and to compute the resonant frequencies;
 - Ansys Q3D for extracting capacitances and inductances;
- **Quantization** by using dedicated software packages:
 - EPR (Energy Participation ratio) + HFSS [npj Quantum Inf 7, 131 \(2021\)](https://doi.org/10.1038/s41534-021-00131-1)
 - LOM (Lumped Oscillator Model) + Q3D [arXiv:2103.10344](https://arxiv.org/abs/2103.10344) [quant-ph]

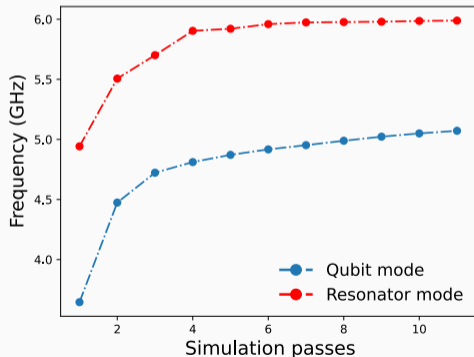

- HFSS Computes EM fields with Finite Element;
- System's eigenmodes, their frequency and the energy stored in each element per mode m ;
- The EPR analysis computes the system eigenmodes $|\psi_m\rangle$ with $m \in \{\text{qubit, resonator}\}$ and computes the energy participation ratio:

$$\rho_m = \frac{\text{Inductive energy in JJ}}{\text{Inductive energy stored in mode } m}$$

- Kerr coefficients:

$$\chi_{nm} = \frac{\hbar \omega_m \omega_n}{4E_J} \rho_m \rho_n$$

- Anharmonicities: $\alpha_m = \chi_{mm}/2$
- Dispersive shifts: χ_{nm} for $n \neq m$.

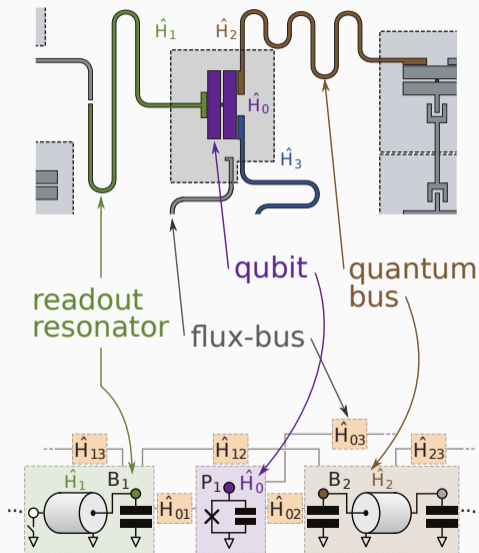

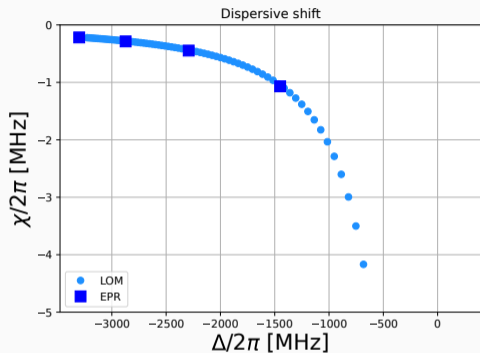

- The method builds on the quantization of lumped elements model;
- The physical layout of the quantum device is systematically partitioned into disjoint cells;
- Each cell can be independently simulated to extract its electromagnetic parameters;
- Taking a subsystem coupled to K neighbors as an example, the Hamiltonian of the composite system:

$$\hat{H}_{full} = \hat{H}_0 + \sum_{n=1}^K \hat{H}_n + \sum_{n=0}^{K-1} \sum_{m=n+1}^K \hat{H}_{nm}$$

$$\text{with } \hat{H}_{nm} = \frac{\hat{Q}_n \hat{Q}_m}{C_{nm}^{eff}} + \frac{\hat{\Phi}_n \hat{\Phi}_m}{L_{nm}^{eff}}$$

where Q , Φ , L and C are extrapolated with Ansys Q3D

	Target	LOM	EPR
JJ Inductance L_J [nH]	10	10	10
Transmon regime E_j/E_c	>50	78.61	79.96
Anharmonicity $\alpha/2\pi$ [MHz]	202	230.62	216.44
Dispersive shift $\chi/2\pi$ [MHz]	0.30	0.31	0.35
Qubit frequency $\omega_q/2\pi$ [MHz]	5000	4995.79	4893.84
Cavity frequency $\omega_r/2\pi$ [MHz]	7400	7481.04	7435.44
Qubit-res coupling C_g [fF]	4	3.93	-

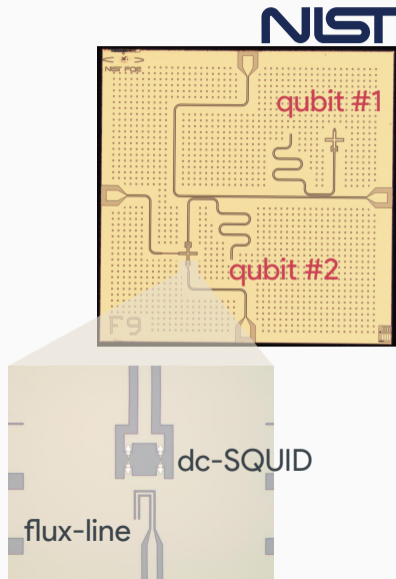

Estimated relaxation time

$$Q_c \sim 4000 \text{ and } Q_i \gtrsim 10^6 \Rightarrow T_1 \sim 70 \mu\text{s}$$

J. Appl. Phys. 104, 113904 (2008)

- Simulation results obtained at different SQUID flux-biases varying $\Delta = \omega_q - \omega_r$;
- Both EPR and LOM analyses are consistent with theory;
- Agreement between EPR and LOM for every parameter of interest within the expected margins.

- Production foreseen in 2024 at FBK after the tuning of the fabrication processes (see Felix Ahrens's talk;)
- Demonstrative two-qubit (not coupled) chip fabricated at NIST (Superconductive Electronics Group):
 - one fixed-frequency resonator driven transmon (qubit #1);
 - one tunable-frequency transmon with dedicated drive-line (qubit #2);
- Fabrication
 - Substrate: 380 nm high-resistive silicon;
 - Metal: 100 nm Niobium;
 - Junctions: Al-AlO_x-Al;
 - Niobium etched also in the JJ area;
- Main goals
 - Validate and calibrate the design and simulation steps;
 - Benchmark for upcoming fabrications in Italy (CNR-IFN, FBK)

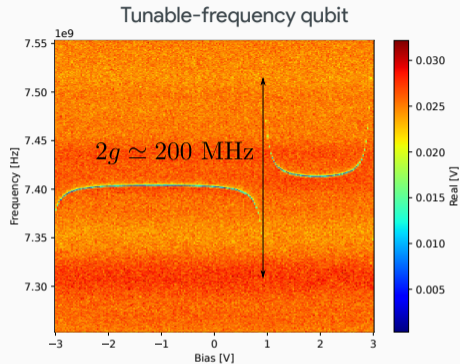

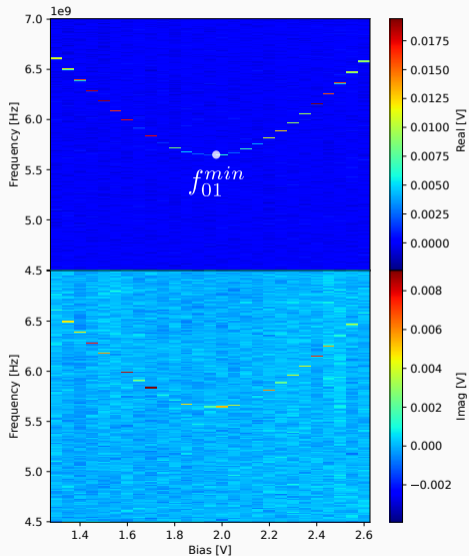

Qubit spectroscopy is performed by sweeping the frequency of the signal applied to the qubit and measuring the signal transmitted through the readout resonator;

Fixed-frequency qubit

	Measured	LOM
f_{01} [GHz]	5.689	5.682
$f_{02}/2$ [GHz]	5.589	5.579
f_{12} [GHz]	5.485	5.476
$f_{01} - f_{12} = \alpha/2\pi$ [MHz]	204	206
L_J [nH]	7.641	7.2

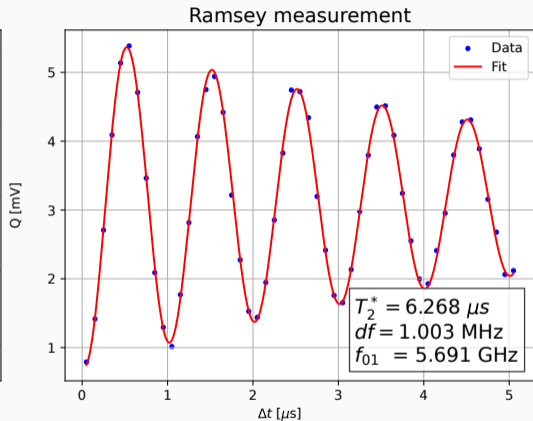

Simulations and measurements are in good agreement

	Measured	LOM
L_J [nH]	8.364	7.9
f_{01}^{min} [GHz]	5.649	5.649
g [MHz]	98	100

Simulations and measurements are in good agreement

- Decoherence times one order of magnitude lower than the one estimated with simulations

- Decoherence times one order of magnitude lower than the ones estimated with simulations;
- Decoherence times compatible with the ones measured for qubit #1;
- Design issue (less likely) or Fabrication issue (more likely);

Fixed-frequency qubit

f_{res} [GHz]	7.573
Q_i	$5.624 \cdot 10^4$
Q_c	$5.063 \cdot 10^3$

Tunable-frequency qubit

f_{res} [GHz]	7.403
Q_i	$4.027 \cdot 10^4$
Q_c	$9.673 \cdot 10^3$

- With $L_j \sim 7$ nH the expected T_1 from Purcell effect is around $24 \mu s \Rightarrow$ low T_1 related to low Q_i (i.e high loss);
- Suspected fabrication issue \Rightarrow different designs in the same wafer showed the same issue;
- New production for double check;

Design simulated with qiskit-metal

- Two Xmon qubits coupled via a cavity bus *Nature* 449, 443–447 (2007)
- Readout resonators capacitively connected at the same transmission line;
- The readout resonators are set around 8 GHz;
- Frequency of the bus resonator set to 5.5 GHz;
- The qubits are flux tunable;
- The main qubits parameters are identical;

Preliminary parameters from Q3D simulations:

Junction inductance L_j [nH]	10
Critical current I_c [nA]	32
Bus resonator capacitance C_R [fF]	368
Qubit shunt C_S [fF]	84
Quantum bus coupling C_c [fF]	1.9
Resonator coupling C_g [fF]	4.6

- A single Xmon qubit design has been simulated and developed during 2023;
- Preliminary fabrication performed at NIST;
- All predicted frequencies and couplings are close to the measured ones;
- Simulations and measurements are in good agreement;
- New wafer production will be done to confirm low T_1 and Q_i was due to fabrication and not design issue;
- New measurement scheduled in 2024 at Unimib, LNF and FBK cryogenics laboratories;
- Same design was adapted for FBK fabrication and produced soon;
- Coupled qubits design is under development
